Topic 2 - Sequences

Def: A sequence of real numbers written (a_n) or $(a_n)_{n=1}^{\infty}$ is an ordered list of real numbers

$$a_1, a_2, a_3, a_4, a_5, \dots$$

Note: The sequence can start from an index that isn't 1, for example you can have $(a_n)_{n=2}^{\infty}$ giving $a_2, a_3, a_4, a_5, \dots$

Ex: $a_n = \frac{1}{n}$

sequence: $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{6}, \dots$

Ex: $a_n = (-1)^n$

sequence: $-1, 1, -1, 1, -1, 1, \dots$

Def: A sequence of real numbers (a_n) is said to converge to a limit $L \in \mathbb{R}$ if for every real number $\varepsilon > 0$, there exists a natural number N such that if $n \geq N$, then $|a_n - L| < \varepsilon$.
 If this is the case, we write $\lim_{n \rightarrow \infty} a_n = L$ or $a_n \rightarrow L$.

If no such L exists, then we say that (a_n) diverges.

PICTURE

Note: N depends on ε . You get a different N for each ε . Some people write $N(\varepsilon)$ instead of N , but we won't do that.

Ex: Consider $a_n = \frac{1}{n}$.

sequence: $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{6}, \frac{1}{7}, \frac{1}{8}, \frac{1}{9}, \dots$

It seems that the limit is $L=0$.

Before we show that $\lim_{n \rightarrow \infty} \frac{1}{n} = 0$, let's get a feel for the definition. With $L=0$ we need to show: "for every $\varepsilon > 0$, there exists $N > 0$ where if $n \geq N$, then $|\frac{1}{n} - 0| < \varepsilon$ "

Let's say $\varepsilon = \frac{1}{1000} = 0.001$

Then if $N = 1001$ we have that

if $n \geq \underline{1001}_N$, then $|\frac{1}{n} - 0| = |\frac{1}{n}| = \frac{1}{n} \leq \frac{1}{1001} < \varepsilon$

Claim: $\lim_{n \rightarrow \infty} \frac{1}{n} = 0$

proof:

Let $\varepsilon > 0$.

Pick a natural number N where $N > \frac{1}{\varepsilon}$.

Then if $n \geq N$ we have that

$$\underbrace{\left| \frac{1}{n} - 0 \right|}_{|a_n - L|} = \left| \frac{1}{n} \right| = \frac{1}{n} \leq \frac{1}{N} < \varepsilon.$$

$$\boxed{\frac{1}{n} > 0}$$

Ex: If $c \in \mathbb{R}$ then $\lim_{n \rightarrow \infty} c = c$.

proof: Let $a_n = c$ for all n .

Let $\varepsilon > 0$.

Set $N = 1$.

Then if $n \geq 1$ we have

$$|a_n - c| = |c - c| = 0 < \varepsilon.$$

Ex: Consider $a_n = (-1)^n$

Let's show that this sequence diverges, that is, it has no limit L .

Claim: $a_n = (-1)^n$ diverges.

proof: We prove this by contradiction. Suppose (a_n) converges to some $L \in \mathbb{R}$.

Let $\varepsilon = 1$.

Then since $(-1)^n \rightarrow L$ there must exist N where if $n \geq N$ then $|(-1)^n - L| < 1$.

case 1: Suppose $L \geq 0$.

Pick an odd integer n_0 with $n_0 \geq N$.

Then, $|(-1)^{n_0} - L| = |-1 - L| = -(-1 - L) = 1 + L \geq 1 = \varepsilon$

$$\begin{array}{l} -1 - L < 0 \\ \text{since } L \geq 0 \end{array}$$

We get a contradiction.

case 2: Suppose $L < 0$.

Pick an even integer n_e with $n_e \geq N$.

Then

$$|(-1)^{n_e} - L| = |1 - L| = 1 - L \geq 1 = \varepsilon$$

$1 - L > 0$
since $L < 0$

because
 $-L > 0$

Again a contradiction

In either case we get a contradiction.

Thus, $(-1)^n$ diverges.

Ex: $\lim_{n \rightarrow \infty} \frac{n}{n+1} = 1.$

proof:

Let $\varepsilon > 0.$

Note that

$$\underbrace{\left| \frac{n}{n+1} - 1 \right|}_{|a_n - L|} = \left| \frac{n}{n+1} - \frac{n+1}{n+1} \right| = \left| \frac{-1}{n+1} \right| = \frac{1}{n+1} < \frac{1}{n}$$

Thus, $\left| \frac{n}{n+1} - 1 \right| < \frac{1}{n}.$

Pick N so that $N > \frac{1}{\varepsilon}.$

Then if $n \geq N$ we get that

$$\left| \frac{n}{n+1} - 1 \right| < \frac{1}{n} \leq \frac{1}{N} < \varepsilon$$

from
above

since
 $n \geq N$

since
 $N > \frac{1}{\varepsilon}$

side commentary:
We need N
where if $n \geq N$
then $\frac{1}{n} < \varepsilon.$
So, need
 $\frac{1}{\varepsilon} < n.$
Pick $N > \frac{1}{\varepsilon}$

Theorem: Limits of sequences are unique.

That is, if $\lim_{n \rightarrow \infty} a_n = L_1$ and $\lim_{n \rightarrow \infty} a_n = L_2$

then $L_1 = L_2$.

proof:

Let $\varepsilon > 0$.

Since $\lim_{n \rightarrow \infty} a_n = L_1$ there exists N_1 where

if $n \geq N_1$ then $|a_n - L_1| < \varepsilon/2$.

Since $\lim_{n \rightarrow \infty} a_n = L_2$ there exists N_2 where

if $n \geq N_2$ then $|a_n - L_2| < \varepsilon/2$.

Pick some m with $m \geq N_1$ and $m \geq N_2$.

This picture can't actually happen since L_1 will equal L_2 but it gives an idea of the construction

Then,

$$\begin{aligned} |L_1 - L_2| &= |L_1 - a_m + a_m - L_2| \\ &\stackrel{\Delta\text{-inequality}}{\leq} |L_1 - a_m| + |a_m - L_2| \\ &\stackrel{|-x|=|x|}{=} |a_m - L_1| + |a_m - L_2| \\ &\stackrel{m \geq N_1 \ \& \ m \geq N_2}{<} \varepsilon/2 + \varepsilon/2 = \varepsilon \end{aligned}$$

We have shown that for any $\varepsilon > 0$
we have that $|L_1 - L_2| < \varepsilon$.

Thus, $|L_1 - L_2| = 0$.

So, $L_1 - L_2 = 0$.

Thus, $L_1 = L_2$.

Def: A sequence (a_n) of real numbers is bounded if there exists a real number $M > 0$ where $|a_n| \leq M$ for all n .

same as
 $-M \leq a_n \leq M$

Theorem: If (a_n) converges,
then (a_n) is bounded.

proof:

Suppose (a_n) converges and $\lim_{n \rightarrow \infty} a_n = L$.

Pick $\varepsilon = 1$.

Then there exists N where
if $n \geq N$, then $|a_n - L| < 1$.

So if $n \geq N$, then

$$|a_n| = |a_n - L + L| \leq |a_n - L| + |L| < 1 + |L|$$

Let

$$M = \max \{ |a_1|, |a_2|, \dots, |a_{N-1}|, 1 + |L| \}$$

Picture with $N=4$

Then, $|a_n| \leq M$ for all n .

So, (a_n) is bounded.

Corollary: If (a_n) is not bounded, then (a_n) diverges.

proof: Contrapositive of above theorem.

Ex: (n^2) diverges.

proof: We show the sequence $a_n = n^2$ is unbounded.

Suppose $M > 0$.

Pick an integer n_0 with $n_0 > \sqrt{M}$.

Then, $n_0^2 > M$.

So, $|n_0^2| > M$.

Thus, (n^2) cannot be bounded by any $M > 0$.

So, (n^2) diverges.

Algebra of sequences theorem:

Let (a_n) and (b_n) be convergent sequences with $\lim_{n \rightarrow \infty} a_n = A$ and $\lim_{n \rightarrow \infty} b_n = B$. Let $\alpha \in \mathbb{R}$.

Then:

- ① (αa_n) converges and $\lim_{n \rightarrow \infty} \alpha a_n = \alpha A$
 - ② $(a_n + b_n)$ converges and $\lim_{n \rightarrow \infty} (a_n + b_n) = A + B$
 - ③ $(a_n b_n)$ converges and $\lim_{n \rightarrow \infty} a_n b_n = AB$
 - ④ If $B \neq 0$ and $b_n \neq 0$ for all n , then $(\frac{1}{b_n})$ converges with $\lim_{n \rightarrow \infty} \frac{1}{b_n} = \frac{1}{B}$
-

proof:

- ① If $\alpha = 0$ then $\lim_{n \rightarrow \infty} \alpha a_n = \lim_{n \rightarrow \infty} 0 = 0$.

So assume $\alpha \neq 0$.

Let $\varepsilon > 0$.

Since $a_n \rightarrow A$ there exists N where if $n \geq N$, then $|a_n - A| < \frac{\varepsilon}{|\alpha|}$.

If $n \geq N$ then

$$\begin{aligned}
 |\alpha a_n - \alpha A| &= |\alpha| |a_n - A| \\
 &< |\alpha| \cdot \frac{\varepsilon}{|\alpha|} \\
 &= \varepsilon
 \end{aligned}$$

So if $n \geq N$, then $|\alpha a_n - \alpha A| < \varepsilon$.

Thus, $\alpha a_n \rightarrow \alpha A$.

② Let $\varepsilon > 0$.

Since $a_n \rightarrow A$ there exists N_1 where
if $n \geq N_1$, then $|a_n - A| < \varepsilon/2$.

Since $b_n \rightarrow B$, there exists N_2 where
if $n \geq N_2$, then $|b_n - B| < \varepsilon/2$.

Let $N = \max \{N_1, N_2\}$.

If $n \geq N$, then

$$\begin{aligned}
 |(a_n + b_n) - (A + B)| &= |(a_n - A) + (b_n - B)| \\
 &\leq |a_n - A| + |b_n - B| \\
 &< \frac{\varepsilon}{2} + \frac{\varepsilon}{2} \\
 &= \varepsilon
 \end{aligned}$$

Thus, $a_n + b_n \rightarrow A + B$.

(3) Let $\varepsilon > 0$.

Note that

$$\begin{aligned} |a_n b_n - AB| &= |a_n b_n - b_n A + b_n A - AB| \\ &\leq |a_n b_n - b_n A| + |b_n A - AB| \\ &= |b_n| |a_n - A| + |A| |b_n - B| \end{aligned}$$

Since (b_n) converges it is bounded so there exists $M > 0$ where $|b_n| \leq M$ for all n .

Since $a_n \rightarrow A$ there exists N_1 where if $n \geq N_1$ then $|a_n - A| < \frac{\varepsilon}{2M}$.

Since $b_n \rightarrow B$ there exists N_2 where if $n \geq N_2$ then $|b_n - B| < \frac{\varepsilon}{2(|A|+1)}$

$|A|+1$ is used
in case $A=0$

Let $N = \max\{N_1, N_2\}$

If $n \geq N$, then

$$|a_n b_n - AB| \leq |b_n| |a_n - A| + |A| |b_n - B|$$

$$\begin{aligned}
&< M \cdot \frac{\varepsilon}{2M} + |A| \cdot \frac{\varepsilon}{2(|A|+1)} \\
&= \frac{\varepsilon}{2} + \frac{\varepsilon}{2} \left(\frac{|A|}{|A|+1} \right) \\
&< \frac{\varepsilon}{2} + \frac{\varepsilon}{2} \\
&= \varepsilon.
\end{aligned}$$

So if $n \geq N$ then $|a_n b_n - AB| < \varepsilon$.

Thus, $a_n b_n \rightarrow AB$.

④ Let $\varepsilon > 0$.

Note that

$$\begin{aligned}
\left| \frac{1}{b_n} - \frac{1}{B} \right| &= \left| \frac{B - b_n}{b_n B} \right| \\
&= \frac{|B - b_n|}{|b_n B|} \\
&= \frac{|b_n - B|}{|b_n| |B|}
\end{aligned}$$

$b_n \neq 0$
for all n
so this
is all
defined

Since $b_n \rightarrow B$ we can find N_1 where if

$$n \geq N_1 \text{ then } |b_n - B| < \frac{|B|}{2}.$$

Thus, if $n \geq N_1$ then

$$||b_n| - |B|| \leq |b_n - B| < \frac{|B|}{2}$$

↑
HW 1

$|x| < c$
iff
 $-c < x < c$

implying

$$-\frac{|B|}{2} < |b_n| - |B| < \frac{|B|}{2}$$

So if $n \geq N_1$ then

$$\frac{|B|}{2} < |b_n| < \frac{3|B|}{2}$$

we will use
this side
below

Again since $b_n \rightarrow B$ we can find N_2 where
if $n \geq N_2$ then $|b_n - B| < \frac{\varepsilon}{2} |B|^2$

Let $N = \max \{N_1, N_2\}$.

Then if $n \geq N$ we have

$$\left| \frac{1}{b_n} - \frac{1}{B} \right| = \frac{|b_n - B|}{|b_n| |B|}$$

$$= \frac{1}{|b_n|} \frac{1}{|B|} |b_n - B|$$

$$\begin{aligned} |b_n| &> \frac{|B|}{2} \\ \frac{1}{|b_n|} &< \frac{2}{|B|} \end{aligned}$$

$$< \frac{2}{|B|} \cdot \frac{1}{|B|} \cdot \frac{\varepsilon}{2} |B|^2$$

$$= \varepsilon$$

Thus if $n \geq N$, then $\left| \frac{1}{b_n} - \frac{1}{B} \right| < \varepsilon$.

So, $\frac{1}{b_n} \rightarrow \frac{1}{B}$.

Def: Let (a_n) be a sequence of real numbers.

We say that (a_n) is monotone increasing if $a_n \leq a_{n+1}$ for all n .

We say that (a_n) is monotone decreasing if $a_{n+1} \leq a_n$ for all n .

We say that (a_n) is monotone if it is either monotone increasing or monotone decreasing

Ex: $a_n = n$

monotone increasing
so its monotone

Ex: $a_n = \frac{1}{n}$

monotone decreasing
so its monotone

Ex: $a_n = c$

monotone increasing and
monotone decreasing

so its
monotone

Monotone convergence theorem

If (a_n) is a bounded monotone sequence, then (a_n) converges.

proof: We will prove this for the case where (a_n) is monotone increasing. The monotone decreasing case is similar.

Since (a_n) is monotone increasing we know that $a_n \leq a_{n+1}$ for all n .

Since (a_n) is bounded there exists $M > 0$ where $|a_n| \leq M$ for all n .

Let $S = \{a_n \mid n \geq 1\} = \{a_1, a_2, a_3, \dots\}$

Let $L = \sup(S)$

We know that L exists by the completeness axiom because the set S is bounded above by M .

We will show $\lim_{n \rightarrow \infty} a_n = L$.

Let $\varepsilon > 0$.

← If (a_n) was monotone decreasing you'd set $L = \inf(S)$

By the inf/sup theorem there exists N where $L - \varepsilon < a_N \leq L$.

Since a_n is monotone increasing we know $a_N \leq a_n$ for all $n \geq N$.

So if $n \geq N$, then

$$L - \varepsilon < a_N \leq a_n \leq L < L + \varepsilon$$

$$\uparrow$$
$$L = \sup\{a_1, a_2, a_3, \dots\}$$

So if $n \geq N$, then $|a_n - L| < \varepsilon$.

because
 $L - \varepsilon < a_n < L + \varepsilon$

Thus, $\lim_{n \rightarrow \infty} a_n = L$

Def: Let (a_n) be a sequence of real numbers. Let $n_1 < n_2 < n_3 < n_4 < \dots$ be a strictly increasing sequence of natural numbers. Then the sequence $(a_{n_k})_{k=1}^{\infty}$ given by

$a_{n_1}, a_{n_2}, a_{n_3}, a_{n_4}, \dots$
is called a subsequence of (a_n)

Ex:

sequence: $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{6}, \frac{1}{7}, \frac{1}{8}, \frac{1}{9}, \frac{1}{10}, \dots$

subsequence: $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}, \frac{1}{32}, \dots$

Monotone subsequence theorem:

If (a_n) is a sequence of real numbers, then there is a subsequence of (a_n) that is monotone.

proof:

We say that the m -th term a_m is a "peak" of our sequence if $a_m \geq a_n$ for all $n \geq m$.

Case 1: Suppose (a_n) has infinitely many peaks. Then listing the peaks by increasing subscripts we get a subsequence of peaks:

$$x_{m_1} \geq x_{m_2} \geq x_{m_3} \geq x_{m_4} \geq \dots$$

with $m_1 < m_2 < m_3 < m_4 < \dots$

So there is a monotonically decreasing subsequence.

Case 2: Suppose (a_n) has finitely many peaks.

Set $s_1 = 1$ if there are no peaks.

Otherwise define s_1 as follows.

Let the peaks be listed by increasing subscripts:

$$a_{m_1} \geq a_{m_2} \geq \dots \geq a_{m_r}$$

where x_{m_r} is the last peak.

Set $s_1 = m_r + 1$.

Thus, a_{s_1} is the term immediately after the last peak.

So, a_{s_1} is not a peak.

Thus, there exists a_{s_2} with

$$a_{s_1} < a_{s_2} \quad \text{and} \quad s_1 < s_2.$$

Then again since a_{s_2} is not a peak there exists a_{s_3} with $a_{s_2} < a_{s_3}$ and $s_2 < s_3$.

Continuing in this way we get a subsequence

$$a_{s_1} < a_{s_2} < a_{s_3} < a_{s_4} < \dots$$

$$\text{with } s_1 < s_2 < s_3 < s_4 < \dots$$

Thus, we have a monotone subsequence.

Bolzano-Weierstrass:

Let (a_n) be a bounded sequence of real numbers. Then there exists a subsequence that converges.

Proof: Let (a_n) be a bounded sequence.

By the monotone subsequence theorem there exists a monotone subsequence (a_{n_k}) . Since (a_{n_k}) is a bounded monotone sequence it must converge by the monotone convergence theorem. $\square$

Ex: $a_n = (-1)^n$ is a bounded sequence.

bounded sequence: $1, -1, 1, -1, 1, -1, 1, -1, \dots$

convergent subsequence: $1, 1, 1, 1, 1, 1, 1, \dots$

Def: Let (a_n) be a sequence of real numbers. We say that (a_n) is a Cauchy sequence if for every $\varepsilon > 0$ there exists $N > 0$ where if $n, m \geq N$ then $|a_n - a_m| < \varepsilon$.

Ex: $\left(\frac{1}{n}\right)_{n=1}^{\infty}$ is Cauchy.

proof:

Let $\varepsilon > 0$.

Pick N so that $N > \frac{2}{\varepsilon}$.

This makes $\frac{1}{N} < \frac{\varepsilon}{2}$.

So if $n, m \geq N$ then

$$\left| \frac{1}{n} - \frac{1}{m} \right| \leq \left| \frac{1}{n} \right| + \left| \frac{1}{m} \right|$$

$$= \frac{1}{n} + \frac{1}{m}$$

$$\leq \frac{1}{N} + \frac{1}{N}$$

$$< \frac{\varepsilon}{2} + \frac{\varepsilon}{2}$$

$$= \varepsilon.$$

Theorem: Let (a_n) be a sequence of real numbers. Then, (a_n) converges if and only if (a_n) is Cauchy.

Proof:

($\Rightarrow$) Let (a_n) be a convergent sequence with $\lim_{n \rightarrow \infty} a_n = L$.

Let $\varepsilon > 0$.

Then, there exists $N > 0$ where if $k \geq N$ then $|a_k - L| < \frac{\varepsilon}{2}$.

Thus, if $n, m \geq N$, then

$$\begin{aligned} |a_n - a_m| &= |a_n - L + L - a_m| \\ &\leq |a_n - L| + |L - a_m| \\ &= |a_n - L| + |a_m - L| \\ &< \frac{\varepsilon}{2} + \frac{\varepsilon}{2} \\ &= \varepsilon. \end{aligned}$$

So, (a_n) is Cauchy.

($\Leftarrow$) Now suppose that (a_n) is Cauchy.
By HW, we get that (a_n) is bounded.
By Bolzano-Weierstrass there exists
a subsequence (a_{n_k}) that converges
to some $L \in \mathbb{R}$.

Let $\varepsilon > 0$.

Since (a_n) is Cauchy, there exists
 $N > 0$ where if $m, l \geq N$ then
 $|a_m - a_l| < \frac{\varepsilon}{2}$.

Since (a_{n_k}) converges to L there
exists $n_{k_0} \geq N$ where $|a_{n_{k_0}} - L| < \frac{\varepsilon}{2}$.

Thus, if $n \geq N$ we get

$$\begin{aligned} |a_n - L| &= |a_n - a_{n_{k_0}} + a_{n_{k_0}} - L| \\ &\leq |a_n - a_{n_{k_0}}| + |a_{n_{k_0}} - L| \\ &< \frac{\varepsilon}{2} + \frac{\varepsilon}{2} \\ &= \varepsilon. \end{aligned}$$

Thus, (a_n) converges to L . $\square$

Note that the $(\Leftrightarrow)$ direction above depended on the completeness of $\mathbb{R}$.
