

Chem 103 May 4, 2009 **Pair-share Quiz1** (bonus) average = 1.7/3 (highest = 3/3)

Problem: Consider the reaction  $2 \text{NO}_2(\text{g}) \rightleftharpoons \text{N}_2\text{O}_4(\text{g})$

Given:

	$\Delta H^\circ_f$ (kJ/mol)	$S^\circ$ (J/K mol)
$\text{NO}_2(\text{g})$	33.2	240.
$\text{N}_2\text{O}_4(\text{g})$	9.2	304

Questions to answer:

- What is  $\Delta G^\circ$  for the reaction? Is it spontaneous?
- At what temperature does it change its spontaneity? (indicate  $>$  or  $<$  for spontaneity to be in effect)
- What's its  $K_{\text{eq}}$ ?

Solution:

a) Use the equation:  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$

where:  $\Delta H^\circ = \sum \Delta H^\circ_f(\text{prod}) - \sum \Delta H^\circ_f(\text{rxts}) = (9.2 \text{ kJ/mol}) - 2(33.2 \text{ kJ/mol}) = -57.2 \text{ kJ/mol}$

$\Delta S^\circ = 304 \text{ Jmol}^{-1}\text{K}^{-1} - 2(240.) = -176 \text{ J/molK}$

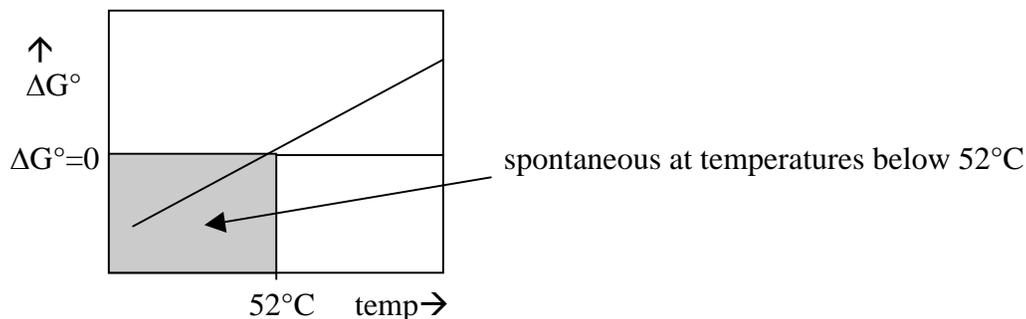

$\Delta G^\circ = -57200 \text{ J/mol} - (298\text{K})(-176) \text{ J/molK} = -57200 + 52450 = -4750 \text{ J/mol}$

spontaneous (ie product favored) since  $\Delta G^\circ < 0$

b) For the temperature at which it changes its spontaneity,  $\Delta G^\circ = 0$  and so...

$$\text{So: } \Delta G^\circ = 0 = \Delta H^\circ - T\Delta S^\circ \Rightarrow T = \frac{\Delta H^\circ}{\Delta S^\circ} = \frac{-57200 \text{ J/mol}}{-176 \text{ J/molK}} = 325 \text{ K} \Rightarrow (325 - 273)\text{K} = 52^\circ\text{C}$$

So at 298 K, which is the same as 25°, it is spontaneous. Up to 52°C it is spontaneous. We can tell because  $\Delta H$  and  $\Delta S$  are both negative and when that is the case the graph is:

at  $T < 52^\circ\text{C}$ , product,  $\text{N}_2\text{O}_4$  is favored.

At  $T > 52^\circ\text{C}$ , reactant,  $\text{NO}_2(\text{g})$  is favored.

(Note: how to actually draw the graph and how to decide whether it's spontaneous above or below the temperature you calculated)

c) The  $\Delta G^\circ = -RT \ln K_{\text{eq}} \Rightarrow K_{\text{eq}} = e^{\frac{-\Delta G^\circ}{RT}} = e^{\frac{-(-4752 \text{ J/mol})}{(8.314 \text{ J/molK})(298\text{K})}} = e^{+1.92} = 6.8$

This is consistent with the idea that it is product favored ( $K > 1$ ) at 298K.

(To more deeply comprehend implications of (c) note: (i) the signs, (ii) the value of R, i.e. 8.314 J/mol K, (iii) that  $K > 1$  for spontaneous and thus product favored reactions).

**Share-Pair Quiz2: Wednesday classroom demonstration** (not yet graded)

One solution per pair: (have the same pairing as last time if possible)

In today's demonstration an aqueous supersaturated solution of sodium acetate ( $\text{NaCH}_3\text{CO}_2$ ) was allowed to crystallize. Initially, we have a supersaturated solution which was obtained by heating 28 g of  $\text{NaCH}_3\text{CO}_2 \cdot 3\text{H}_2\text{O}$  crystals. We noted that upon reaching  $54^\circ\text{C}$ , the crystals dissolved into a liquid, dissolving into its own water of hydration! The solution was allowed to cool down to room temperature. This supersaturated solution was stable enough to bring to class, but upon being pored out of the test tube, it instantaneously crystallized. The thermometer initially read  $24^\circ\text{C}$  for the liquid solution, but when it instantaneously solidified, it read  $54^\circ\text{C}$ ... and no higher.

From what you observed, write down the following:

- 1) The chemical equation for describing the process observed.
- 2) deduce the signs of  $\Delta H$ ,  $\Delta G$  and  $\Delta S$  for the process of crystallization just observed: (just say if it's expected to be + or -)
- 3) Draw a sketch of the graph of  $\Delta G$  vs  $T$  for this observed process.
- 4) Suppose that you can use the following magnitudes for process of crystallization of  $\text{NaCH}_3\text{CO}_2$ , what is the value of  $K_{\text{eq}}$   
 $|\Delta H^\circ| = 25 \text{ kJ/mol}$  ;  $|\Delta S^\circ| = 45.6 \text{ J mol}^{-1}\text{K}^{-1}$
- 5) What is  $\Delta G$  for the reaction if  $T = 500\text{K}$ , assuming that it's at equilibrium?

New Question:

- 6) What is  $\Delta G^\circ$  for the reaction at  $T = 500\text{K}$ ?

**Solution:**

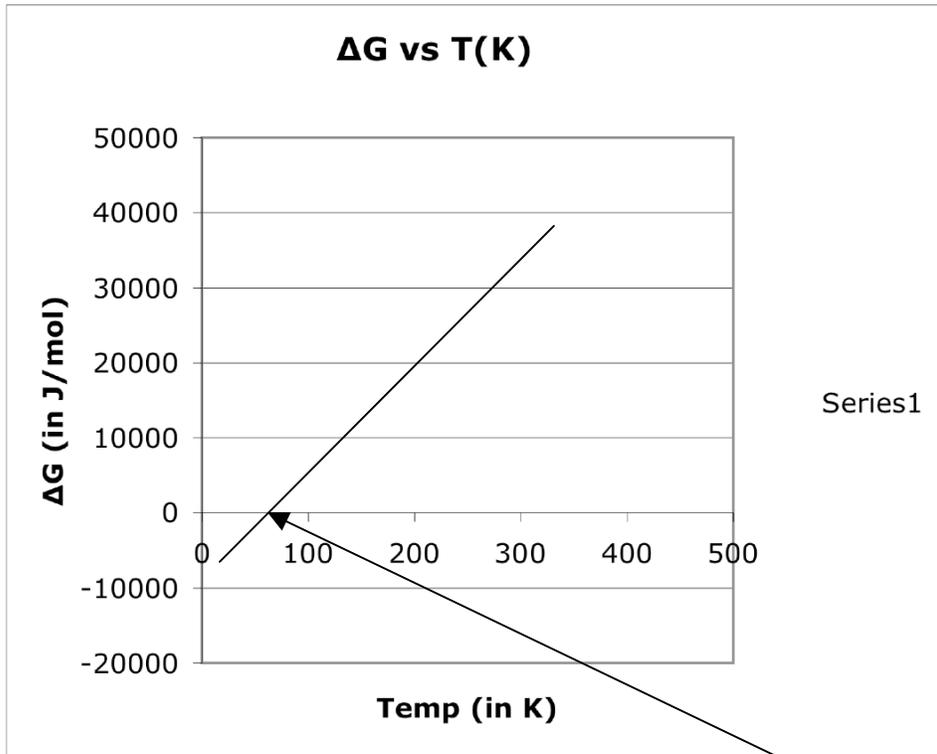

2)  $\Delta H$  is negative (exothermic since it got hotter to the touch),

$\Delta G$  is negative since it was quite spontaneous.

$\Delta S$  is negative since the process of converting from a liquid to a solid increases the order of the system and therefore  $\Delta S = S_{\text{final}} - S_{\text{initial}} = \text{negative}$  since  $S_{\text{final}}$  is less than  $S_{\text{initial}}$ .

3) The  $\Delta G$  vs  $T(\text{K})$  graph looks like that below:

It is seen that the conversion of sodium acetate solution to sodium acetate crystals is spontaneous only below a certain temperature. That temperature is  $54^\circ\text{C}$  from our class data.

4) OK,  $\Delta H^\circ = -25000 \text{ J/mol}$ ,  $\Delta S^\circ = -45.6 \text{ J mol}^{-1}\text{K}^{-1}$  (remember that the reaction was **exothermic** and felt hot to the touch, and that the liquid crystallized into a solid).

$$\text{so } \Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -25000 \text{ J/mol} - (298\text{K})(-45.6 \text{ J mol}^{-1}\text{K}^{-1}) \\ = -25000 \text{ J/mol} + 13590 \text{ J/mol} = -11,400 \text{ J/mol} = -11.4 \text{ kJ/mol}$$

$$K = \exp\left(-\frac{\Delta G^\circ}{RT}\right) = \exp\left(-\frac{-11400\text{J/mol}}{(8.314\text{J/molK})(298)}\right) = 100$$

5)  $\Delta G = 0$  (since it's at equilibrium).

$$6) \Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -25,000 \text{ J/mol} - (500\text{K})(-45.6 \text{ J/molK}) = -2200 \text{ J/mol} = -2.2 \text{ kJ/mol}.$$
